

TRANSMITTER BLOCK DIAGRAM

The antenna switch circuit consists of two PIN diodes (CR161 and CR162), a pi network (C126, L161, and part of C162), and one current limiting resistor (R163). In the transmit mode, TX B+ is applied to the circuit to bias the diodes "on". The shunt diode (CR161) shorts out the receiver port, and the pi network, which operates as a quarter wave transmission line, transforms the low impedance of the shunt diode to a high impedance at the input of the harmonic filter. In the receiver mode, the diodes are both off, and hence, there exists a low attenuation path between the antenna and receiver ports.

The harmonic filter consists of part of C122, L121, and C123. This filter attenuates the harmonic of the module to a level better than -55 dBc.

To optimize the transmitter and receiver performance into the antenna, a network is used to match the antenna's impedance to the harmonic filter. The network is made up of C125 and L122.

The power control circuit consists of the networks associated with U151, Q151, Q155, and U111.

U111 is a directional coupler which detects the forward power of the power module U101. The couple has 21 dB \pm 1 dB coupling at port 2. The RF voltage at the coupler port 2 is rectified by CR111, C111, R114, C112, and is applied to U151A. This signal is amplified by U151A and applied to summing and integrator amplifier U151B.

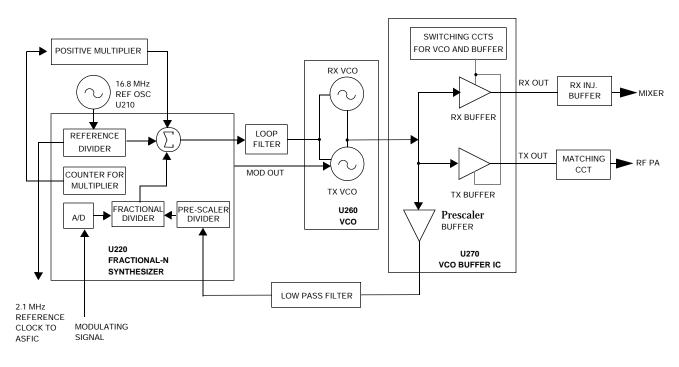

The voltage at the second input of the summing amp is supplied by DAC U400-P9. This DAC is controlled by the microprocessor and provides the reference voltage for the control loop.

The error voltage at the input of U151B-13 produces a voltage at its output which is in turn applied to the drivers Q151, Q152. The voltage from Q151 collector is applied to the controlled stage of the power module.

Frequency Generation Unit

The Frequency Generation Unit (FGU) consists of the following major sections: the high stability reference oscillator (U210), fractional-N synthesizer (U220), VCO (U260), VCO buffer IC (U270) and Rx injection buffer (Q280, Q281 and the surrounding components). The VCO provides the carrier frequency for the transmitter (U270 Tx output) and provides the local oscillator (LO) injection signal for the Rx injection buffer (U270 Rx output). The phase-locked loop (PLL) circuit is provided by the fractional-N synthesizer IC.

The output of the VCO is amplified by the prescaler buffer, routed through a low-pass filter, and applied to the prescaler dividers of the synthesizer. The divide ratios are determined from information stored in memory and bussed to the synthesizer by way of the microcontroller. The divide ratio determines the VCO frequency. The resulting VCO buffer signal is applied to a comparator located in the synthesizer. The synthesizer comparator also receives a reference frequency by

FGU CIRCUITS

way of reference divider input from the 16.8 MHz temperature-compensated reference oscillator. If the two frequencies differ, the synthesizer generates a control (error) voltage causing the VCO to change frequency.

Modulation of the carrier is achieved by using a 2-port modulation technique. The deviation of the low frequency tone, such as PL/DPL, is achieved by injecting the signal into an analog/digital circuit in the synthesizer. The resulting digitized signal is then modulated by the fractional N divider; this generates the required deviation. The deviation of the high frequency tone is achieved by modulating the modulation varactor on the VCO. To cover a very wide bandwidth, the VCO control voltage is stepped up by using a positive multiplier circuit. A 13-V supply powers the phase detector circuitry. The VCO signal is amplified by the integrated buffer amplifier of the VCO buffer. The buffer IC Tx output signal is filtered and channeled to the RF PA (U101). The buffer IC Rx output signal is connected to the Rx injection buffer. The output signal of that buffer is supplied to the receiver first mixer (U50) as the injection signal.

Controller

The GTX/GTX LTR/LTS 2000 controller is an open architecture which consists of:

- U709, Motorola 68HC11K1 microprocessor
- U701, Audio Signalling Filter Integrated Circuit, ASFIC
- U703, 1 Kbyte EEPROM
- U705, 128/256 Kbyte OTP/FLASH ROM
- U706, 8/32 Kbyte Static RAM
- U707, LCD Display Driver
- U704, 5 V Voltage Regulator
- U550, Hear Clear

U709, U703, U705, U706 and U707 are powered by U704. U701 is powered from a 5V Regulator (U708) on Radio Module. In addition to the external memory devices, U709 has 768 bytes of RAM and 640 bytes of EEPROM.

Functions

The microprocessor has two basic functions: interfacing with the outside world, and controlling the internal workings of the radio. The microprocessor interfaces directly with the keypad, side buttons, PTT, rotary switch, low battery indicator, EXT PTT and volume sense. The microprocessor constantly monitors these inputs and interprets any changes into commands that control the rest of the radio. Some control functions it performs include loading the synthesizer with the desired RF frequency, turning the RF PA on or off, enabling and disabling audio and data paths and generating tones. Operations and operating conditions within the radio are interpreted by the microprocessor and fed back to the operator as visible (the display) or audible (alert tone) indications of current status.

Normal Operation

The regulated 5V output from U704 powers the microprocessor (U709) and the rest of the digital IC except ASFIC (U701). The microprocessor's clock is generated by the ASFIC, which has a built-in programmable clock synthesizer.

Clock Synthesizer

Upon power-up and assuming that the ASFIC receives a proper 2.1 MHz input on U701-P38 (which comes from the transceiver board), the ASFIC outputs a 7.776 MHz CMOS square wave (0-5Vpp logic) on U701-P30, which connects to the EXTAL input of the microprocessor, U709-P73. The microprocessor operates at 1/4 of this frequency, which in this case computes to 1.944 MHz. In particular, the E clock output (U709-P72) will be a 50% duty cycle square wave at this frequency.

Bus Operation

The microprocessor operates in expanded memory mode and executes firmware contained in OTP/ FLASH ROM, U705. The microprocessor uses a nonmultiplexed address data bus, consisting data lines D0 through D7 and address lines A0-A17. In addition, the microprocessor has integrated chip-select logic so that external memories can be accessed without the need for external address decoder gates. These chip-select signals are provided by U709-P28 and P29.

When the controller board is functioning normally, microprocessor's address and data lines should be toggled at CMOS logic levels. Specifically, the logic-high levels should be between 4.8 and 5.0V, and the logiclow levels should be between 0 and 0.2V.

RAM

The on-chip 768 byte static RAM from U709 provides some scratch-pad memory, with the bulk of it coming from the external 8 or 32Kbyte SRAM, U706. External SRAM accesses are indicated by the U709-P28. Normally SRAM is accessed less often than the OTP/ FLASH ROM, U705; i.e. the number of transitions per second on U705 chip select (pin 30) should be 5-15 times higher than those on U706 pin 20.

EEPROM

The radio codeplug storage is provided by U709 internal 640 byte EEPROM, with an additional 4K byte of memory space provided by external EEPROM, U703. There are three basic types of codeplug information: information on the trunked system on which the radio is authorized to operate; information on the conventional system, which is either of the repeater or talkaround type on which the radio is authorized to operate, and information on the configuration and tuning of the radio itself. Tuning information is normally located in the internal EEPROM of U709.

SPI Interface

The microprocessor communicates with several ICs and modules through a dedicated on-chip serialperipheral-interface (SPI) port which consists of transmit data line MOSI (U709-P1), receive data line MISO (U709-P80), and clock line SCK (U709-P2). In addition, each IC that can be accessed by the microprocessor using the SPI read/write select line associated with it. The ICs or circuits and their associated select lines are:

- EEPROM (U703) with select line U709-P3
- ASFIC (U701) with select line U709-P34
- LCD Driver (U707) with select line U709-P23
- OTP/FLASH ROM (U705) with select line U709-P29
- SRAM (U706) with select line U709-P28
- Transceiver Board Synthesizer (U201) with select line U709-P35
- Transceiver Board DAC IC (U400) with select line U709-P26

The LCD Driver uses the master out/slave in (MOSI) line to send data to the display driver IC, and the master in/slave out (MISO) line to send data back to the microprocessor (U709). Note, however, that the keypad (or any other SPI device) can never initiate display data; the microprocessor is at all times the SPI master device. Thus the MOSI line and MISO line are always in the master configuration.

LED Control

The bicolor LED located on the top of the radio is indirectly activated by SPI of U709 via the DAC IC (U400) on Transceiver Board. When either input to the dual NPN transistor (U410) is at logic high, the corresponding output pin (pin 6 for the green LED, pin 3 for the red) should be at approximately 4.3 Vdc. Note that it is possible to have both LED outputs on simultaneously, in which case the LED emits a yellow/orange light.

Audio & Data Circuitry

The transmit and receive audio paths are disabled in the standby mode and selectively enabled by the microprocessor when the radio transmits or receives a signal. Also, there are minor differences in the functioning of both paths depending on whether an internal or external (accessory) microphone/speaker is being used. The radio constantly monitors the received data path for control-channel data in trunking operation or sub-audible data in conventional operation.

External PTT Sense Circuits

On connecting an external MIC through connector J3, external PTT sense transistor Q408 switches "ON" when the external PTT switch is closed. Q408 collector voltage is monitored by U709-P4. When collector voltage is logic "HIGH", the microprocessor configures the radio for transmit mode. In PTT equipped accessories, the PTT switch is series connected with the external MIC element.

MIC Amplifier

MIC audio from internal MIC MK401 is coupled through C429, L404, J3 and L403 to the MIC buffer circuit U405-1. External MIC plug insertion mechanically disconnects the internal MIC. External MIC audio is coupled through L403 to the MIC buffer input. The buffer will route the MIC audio into MIC IN (U701-B8) through flex and connectors J200 and J700. Inside the ASFIC, the MIC audio is filtered to eliminate components outside the 300-3000 Hz voice band, pre-emphasized, and then limited. The limited MIC audio is then routed through a summer, which is used to add in PL or DPL sub-audio band modulation, and then to a splatter filter to eliminate high frequency spectral components generated by the limiter. After the splatter filter, the audio is routed to the 8 bit modulation attenuators, which are tuned in the factory of the field to set the proper amount of FM deviation. The TX audio emerges from the ASFIC at U701-J4 and is dc coupled and applied through flex and connectors J700 and J200 to the synthesizer (U201) pin 8.

TX Data Circuits

There are four major types of transmit data: sub-audible data (PL/DPL/Connect Tone) that gets summed with voice, high speed data for trunking control channel communication, DTMF data for telephone communication in trunked and conventional systems, and MDC data for use in Motorola proprietary MDC systems. The deviation levels of the latter three types are tuned by a 5-bit digital attenuation inside the ASFIC. For each data type and each band split, there is a distinct set of tuning values that are programmed into the ASFIC before the data is generated and transmitted.

Sub-Audible Data (PL/DPL)

Sub-audible data is composed of low-frequency PL and DPL waveforms for conventional operation and connect tones for trunked voice channel operation. (The trunking connect tone is simply a PL sine wave at a higher deviation level than PL in a conventional system). Although it is referred to as "sub-audible data", the actual frequency spectrum of these waveforms may be as high as 250 Hz, which is audible to the human ear. However, the radio receiver filters out any audio below 300 Hz, so these tones are never heard in the actual system.

Only one type of sub-audible data can be generated by U701 at a time. The process is as follows: using the SPI, the microprocessor programs the ASFIC (U701) to set up the proper low-speed data deviation and select the PL or DPL filters. The microprocessor then generates a square wave from U705-P6 which strobes the ASFIC PL_CLK (U701-C3). For encode input at twelve times the desired data rate. (For example, for a PL frequency of 103 Hz, the frequency of the square wave at U701-P20 would be a1236 Hz). This derives a tone generator inside U701, which generates a staircase approximation to a PL sine wave or DPL data pattern. This internal waveform is then low-pass filtered and summed with voice or data. The resulting summed waveform then appears on U701-H8 (VCO_ATN), where it is sent to the transceiver board as previously described for transmit audio.

High-Speed Data

High-speed data refers to the 3600 baud data waveforms (ISWS AND OSWS) used in a trunking system for high-speed communication between the radio and the central controller. To generate an ISW, the microprocessor (U709) first programs the ASFIC (U701) to the proper filter and gain settings. It then begins strobing U701-G1 (Trunking Clock In) with a square wave (from U709-P5) at the same baud rate as the data. The output waveform from 5-3-2 State Encoder of U701 is then fed to the post-limiter summer block and then the splatter filter. From that point it is routed through the mode attenuator and then out of the ASFIC to the transceiver board via VCO_ATN (U701-H8).

DTMF Data

DTMF data is a dual-tone waveform used during phone interconnect operation. They are divided into low-group and high-group tones. The high-group tone is generated by U709-P5 strobing U701-G1 at six times the tone frequency for tones less than 1440 Hz, or twice the frequency for tones greater than 1440 Hz. The lowgroup tone is generated by U709-P7 strobing U701-G2 (DTMF Clock) at six times the tone frequency. Inside U701 the low-group and high-group tones are summed (with the amplitude of the high-group tone being approximately 2dB greater than that of the low-group tone) and then pre-emphasized before being routed to the summer and splatter filter. The DTMF waveform then follows the same path as was described for high speed data.

MDC Data

The MDC signal follows exactly the same path as the DTMF high-group tone. MDC data utilizes MSK modulation, in which a logic zero is represented by one cycle of a 1200 Hz sine wave, and a logic one is 1.5 cycles of an 1800 Hz sine wave. To generate the data, the microprocessor (U709) first programs the ASFIC (U701) to the proper filter and gain settings. It then begins strobing U701-G1 with a square wave (from U709-P5) at the same baud rate as the data. The output waveform from U701 is fed to the post-limiter summer block and then the splatter filter. From that point it is routed through the mode attenuator and then out of ASFIC to the transceiver board via VCO_ATN (U701-H8).

RX Audio Processing and Digital Volume Control

The radio's RF circuit are constantly producing an output at the Detected Audio line. Whenever the radio is in trunked standby mode, it is processing data from the control channel; while in conventional standby mode, it is always monitoring the squelch line and/or subaudible data. The detected audio from the transceiver board enters the controller board at connector J700 pin 4. In addition to the detected audio line, the transceiver board also provides a squelch noise from U51-P30 into the ASFIC squelch-detect circuitry via U701-H7. When the microprocessor determines that it has received the proper data or signal type for unsquelching, it sets up the receive audio path and sends data to U701 to do the same within.

The detected audio will enter U701 through RX IN (pin H6) and PL IN (pin J7) for further processing. Inside the IC, the signal first passes through a low-pass filter to remove any frequency components above 3000 Hz and then a high-pass filter to strip off any sub-audible data below 300 Hz. Next, the recovered audio passes through a de-emphasis filter to reduce the effects of FM noise. Finally, the IC amplifies the audio and passes it through the 8-bit programmable attenuator whose level is set, depending on the value of the volume control. The microprocessor (U709) programs the value of the 8-bit attenuator in accordance with the voltage sensed at the volume potentiometer, which is connected to U709-P48. This pin is one of the eight channels of U709's 8 bit A/D convertor. After passing through the 8-bit digital attenuator, the audio goes to a buffer amplifier and then exits at U701-J4, where it is routed to the Audio power amplifier circuit in the transceiver board.

GTX/GTX LTR/LTS 2000 Portable Radios Service Manual

Controller

Audio Power Amplifier

Resistor R466 sets the input impedance to U409-P2 of the audio power amp. The audio PA circuit is a bridged-tied-load (BTL) configuration with fixed gain of 40dB, developing 500mW (rated audio power) output at less than 5% harmonic distortion into the 16 Ohm internal speaker LS401 with nominal 7.5 V DC battery supply. Maximum audio power output is greater than 1.2 W.

Audio PA Muting and Output Protection

PNP transistor Q410, the audio PA power switch, driven by NPN darlington transistor Q411, the PA mute amp, controls Vcc supply to Audio PA U409-P1. U701-A3 is connected to Q411 base, controlling audio PA Vcc supply. Resistors R489 and R490, PNP transistor Q412 and the current sense circuit monitor current supplied to audio PA U409-P1. Worst case audio PA current (at 9 V DC battery voltage, maximum volume and full system deviation) does not exceed 450 mA at the nominal 16 Ohm load. Resistor R488 and capacitor C461 provide an RC time delay for U405-2, a monostable multivibrator circuit. A 2.5 V DC reference voltage is fed to U405-2-P6. On radio power-up, and in normal operation U405-P7 monostable multivibrator output is logic "LO" pulling Q411 emitter to Vee with the audio PA controlled by U701-A3. Should U409-P5 and/or U409-P8 become shorted to each other or to the ground (Vee), current consumption exceeds 500 mA (approximately) and Q412 collector. When U405-2-P5 voltage rises higher than the U405-2-P6 reference voltage (rise time is less than 50 µsec), U405-2 is triggered and U405-2-P7 dc output voltage is switched to 4Vdc, effectively biasing Q411 into cutoff and turning off the audio PA power switch Q410. U405-2-P7 remains in this state for 15 msec, then reset to logic "LO" state. Average power dissipation in the audio PA circuit components is helped to a low level by the low duty cycle (less than 0.3%) of the audio PA protection circuit. The cycle repeats until the audio PA output short is removed.

Receive Data Circuits

The ASFIC (U701) decodes all receive data, which includes PL, DPL, low-speed trunking, MDC, and highspeed trunking data. The "decode" process for each data type typically involves low pass or band pass filtering, signal amplification, and then routing the signal to a comparator, which outputs a logic zero or one signal. The detected audio from the transceiver board is routed to U701-H6 and J7 through coupling cap C435. Inside U701, the data is filtered according to the data type (HS data or LS data, then hard-limited to a 0-5V digital level. The high-speed limited data output (MDC and trunking high-speed) appears at U701-G4, where it connects to U709-P11. The low speed limited data output (PL, DPL and trunking low-speed) appears at U701-A4, where it connects to U709-P10.

Alert Tone Circuits

When the microprocessor needs to give the operator feedback (for a good key press or for a bad key press) or radio status (trunked system busy, low battery condition, phone call, circuit failures), it sends an alert tone to the speaker. It does so by sending data to U701, which sets up the audio path to the speaker for alert tones. The alert tone itself can be generated in one of two ways: internally by the ASFIC, or externally using the microprocessor and the ASFIC. The allowable internal alert tones are 300, 900, and 1800 Hz. For external alert tones, the microprocessor can generate any tone within the 100-3000 Hz audio band. This is accomplished by the microprocessor toggling the output line U709-P7, which is also the same line used to generate low-group DTMF data. Inside the ASFIC, this signal is routed to the external input of the alert tone generator. The output of the generator is summed into the audio chain just after the RX audio deemphasis block. The tone is then amplified and filtered before passing through the 8-bit digital volume attenuator. The tone exits at U701-J4, and is routed to the audio PA circuitry in the transceiver board.

Hear Clear IC

The Hear Clear (HC) is typically used for 900 MHz radios. The HC has three main circuit blocks within the IC.: 1) Compressor, 2) Flutter Fighter, 3) Expander Circuits. There are six enable/control lines on the HC which determine its mode of operation. The remaining five lines are controlled by the HC_CNTL line of DAC U1400-15. The table below summarizes the logic controls and the IC states.

			Logic State			
Name	Ref.Des	Set By	TX1	RX1	TX2	RX2
ICENABLE	U550-C4	SWB+	1	1	Х	1
FFENAB	U550-E3	HC_CNTL	1	1	Х	0
LODSAB	U550-A5	HC_CNTL	1	1	1	х
HIENAB	U550-C2	GND	0	0	Х	0
HCIDSAB	U550-B6	HC_CNTL	1	1	1	1
CPNENAB	U550-D1	HC_CNTL	1	1	Х	0

Table 2-1.

TX1: transmit mode with carrier squelch, PL or DPL.

RX1: receive mode with carrier squelch, PL or DPL.

TX2: transmit mode with all data HST, MDC, MPT & DTMF.

RX2: receive voice with all data HST, MDC, MPT & DTMF.

Transmit Path for Radio with Hear Clear

TX audio signal comes from microphone and enters the ASFIC "MIC" pin U701-B6. The audio signal from the ASFIC is routed to ASFIC pin U701- H5, from where it leaves the ASFIC and enters the Hear Clear compressor at pin U550-D3. The compressed signal leaves Hear Clear at pin U550-F3 "COMP OUT" where it is routed back to the ASFIC TX pin U701-C7, C561 provides AC coupling. Inside the ASFIC, the signal is routed through a LPF and HPF that limits the signal between 0.3 - 3KHz. The signal is then pre-emphasized and exits the ASFIC "PRE_AMP" at pin U701-C8, and routed back to ASFIC at LIM pin U701-E8 where it is routed through the limiter, splatter filter, and two attenuators which set the amplitude (deviation level) of the signal.

The purpose of having a compressor in the transmit mode is twofold: 1) improve S/N ratio for low level audio and 2) maintain the same dynamic range of 12.5 KHz bandwidth channel as obtained in the 25 KHz channel.

The compressor raises low level signals and lowers high level signals. The compressor circuit produces a signal whose output voltage at pin U550-F3 is based on the input voltage of the signal at pin U550-D3. It is not a function of the frequency (as in pre-emphasis). The transfer function is: COMP OUT==SQRT(80*MIC_IN.

Note: 80 mV input provides 80mV output: e.g

20 mV input == 40 mV output

80 mV input == 80 mV output

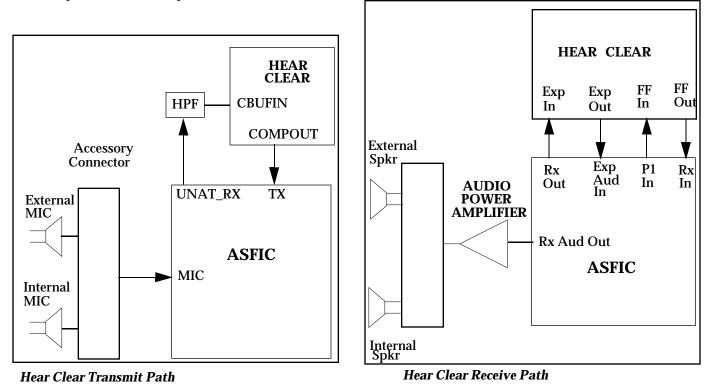

150 mV input == 110 mV output

Receive Path for Radio with Hear Clear

The audio signal enters the Hear Clear controller from BBR signal "DET_AUDIO" at pin U51-28. The discriminator audio signal "DISC" enters the Hear Clear Flutter Fighter pin U550-U4 "FFIN" through capacitors C500 and C567. C567 is a part of a noise sampling circuit consisting of components- C567, R556, R553, C564, R555, R557 and C565; and Hear Clear ports "CLIP-REF", "NFILIN", "NFILOUT" and "NOISHLD".

After exiting Hear Clear at the "FFOUT" pin U550-F4, the signal enters ASFIC at "RX" pin U701-H6. Within the ASFIC, the signal passes through LPF and HPF limiting the audio bandwidth to 0.3-3 Khz, de-emphasis and exit the ASFIC at "UNAT_RX" pin U701-H5.

After exiting the ASFIC at "UNAT_RX", the signal passes through the AC coupling capacitor C550 and is routed to the Hear Clear pin "EXPIN" U550-C1, which is Expander input buffer. The Expander output signal "EXPOUT" at pin U550-A2 is a normalized received audio signal which is routed back to the ASFIC through the AC coupling capacitor C560 for volume adjustment at pin "EXP_AUDIO" U701-J5. The adjusted signal exits ASFIC at pin "RX AUDIO" U701-J4 and is routed to the Audio Power Amplifier.

Controller

The purpose of Flutter Fighter is to sample the amount of Noise in the receive audio between 10 - 20 Khz using the Noise Filter IN pin "FFIN" U550-E4, Noise Filter Out the leg "FFOUT" U550-C6 and Noise Hold the pin "NOISHLD" U550-D5. In addition, it monitors the rate of change of RSSI (Receive Signal Strength In) signal in "RSSI IN" pin U550-F5. The discriminated audio signal DISC enters into the Hear Clear IC at "FFIN" U550-E4. The circuit then reduces the amount of popping Noise associated with fading. The improved audio exits the IC at "FFOUT" pin U550-F4.

The expander is used after de-emphasis but before the ASFIC volume attenuation. The Expander purpose is to transpose the compressed audio back to "normal" audio. As with the compressor circuit, the expander circuit adjusts the amplitude of a signal based upon its input amplitude, NOT its frequency.

Note that an input of 191 mV will exit as 191 mV. While a smaller signal will be made even smaller and a signal larger than 191 mV will exit "EXPOUT" even larger.

Example:

100 mV EXPIN == 52 mV EXPOUT

191 mV EXPIN == 191 mV EXPOUT

250 mV EXPIN == 327 mV EXPOUT

Note: this operation is NOT a function of frequency between .3-3 Khz.

Hear Clear IC (U550) Data Signal Routing

While, transmitting, all signals bypass the Hear Clear Compressor.

While receiving, subaudible signals PL/DPL/LST go through the Flutter Fighter and ASFIC. Inside the ASFIC, the sub-audible signaling is separated from the voice for decoding. Sub-audible signaling never goes through the expander.

While receiving, other signals HST/MDC/MPT (not sub-audible), the Flutter Fighter is set to "pass through mode": the signal is routed from "FFIN" to "FFOUT" without any adjustment.

Section 3 Accessory

Overview

The remote speaker microphone is an accessory available with the GTX/GTX LTR/LTS 2000 portable radios. This section provides a general description of the remote speaker microphone and describes the operation, handling precautions, and maintenance of this accessory.

Description

Model HMN9725 Remote Speaker Microphone includes a speaker, a microphone, a push-to-talk (PTT) switch and associated circuitry. A cable, terminated with a special plug, is provided for attaching to the accessory connector on the portable radio.

When the remote speaker microphone is attached to the radio, the speaker in the radio is disabled, and receiver audio is connected to the accessory speaker. Similarly, the accessory microphone is connected to the transmitter, and the accessory PTT switch can now control the PTT function in the radio. The radio microphone and PTT switch are still operational, but you can listen to the radio only through the accessory speaker.

> **IMPORTANT** Observe safety information in the radio operating instructions.

Operation

- 1. Attach the microphone's accessory connector to the accessory connector on top of the radio.
- 2. While listening to the accessory speaker, turn the radio on.
- 3. Operate radio according to operating instructions supplied with the radio.

NOTE The microphone will perform best if it is worn as shown in Figure 3-1.

Handling Precautions

To avoid damage to circuits, observe the following handling, shipping, and servicing precautions.

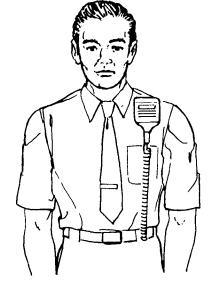

Figure 3-1. Ideal Microphone Position

- Prior to and while servicing a remote speaker microphone, particularly after moving within the service area, momentarily place both hands on a bare metal, earth-grounded surface. This will discharge any static charge which may have accumulated on the person doing the service.
- Whenever possible, avoid touching any electrically conductive part of the unit with your hands.

NOTE Wearing a conductive wrist strap (Motorola No. RSX-4015A) will minimize static buildup during servicing.

WARNING

While wearing a conductive wrist strap, be careful near high voltage sources. The good ground provided by the wrist strap will also increase the danger of lethal shock from accidentally touching high voltage sources.

• When servicing a unit, avoid carpeted areas, dry environments, and certain types of clothing (silk, nylon, etc.) because they contribute to static buildup.

Maintenance

- All electrically powered test equipment should be grounded. Apply the ground lead from the test equipment to the unit before connecting the test probe. Similarly, disconnect the test probe prior to removing the ground lead.
- If the microphone cartridge is removed from the unit, place it on a conductive surface, such as a sheet of aluminum foil which is connected to ground through 100k ohms of resistance.

WARNING

If the aluminum foil is connected directly to ground, be cautious of possible electrical shock from contacting the foil at the same time as other electrical circuits.

- When soldering, be sure the soldering iron is grounded
- Prior to replacing circuit components or touching the microphone cartridge, be sure to discharge any static buildup. Since voltage differences can exist across the human body, it is recommended that only one hand be used if it is necessary to touch the microphone cartridge and associated wiring.

• Replacement microphone cartridges should be kept in conductive packaging until they are placed in unit.

Maintenance

Refer to the schematic diagram (shown in Figure 3-2), the exploded view (shown in Figure 3-3, on page 3-3), and the parts lists. Every part in the microphone is identified and illustrated for assistance in removal and replacement.

If necessary, the external surfaces of the remote speaker microphone may be cleaned with a 0.5% solution of mild dishwashing detergent in water (one teaspoon of detergent in a gallon of water).

Section 5 Radio Diagnostic Utilities

Test Mode/Entry

Test Mode allows radio checks to be performed in the field. To provide a level of protection to the Test Mode entry, proceed according to the following sequence:

- 1. Place radio in TRUNKING operation mode and wait for 6 seconds. (See Quick Start card for instructions on how to enter that mode.)
- 2. Turn radio off.
- 3. Remove battery from radio.
- 4. Plug the 25-pin end of the HKN9857 programming cable into the RIB. The other end of this cable has a battery eliminator.
- 5. Put the battery eliminator in place of the radio battery.
- 6. Verify that RIB is off.
- 7. Turn radio power supply (7.5 V DC) on.

NOTE

You may use the programming cable battery as external power supply for the radio.

8. Turn radio on.

The radio enters Test Mode operation:

- Speaker unmutes.
- One beep is heard to indicate operation on the first test frequency (default).
- Display shows "4 1".

CHANNEL MODE (4 IS INITIAL MODE)

Test Mode/Channel Selection

Use the PTT switch for channel selection. A short press and de-press on the PTT switch (button-like push) will advance the radio to the next channel (cyclical). Seven channels are available during test mode, as shown in the table below.

Channel Number	Rx Frequency	Tx Frequency	Display
1	935.0125 MHz	896.0125 MHz	"M 1" (2)
2	938.0125 MHz	899.0125MHz	"M 2" (2)
3	941.0000 MHz	902.0000MHz	"M 3" (2)
4	CC1 (1)	CC1-45 MHz	"M 4" (2)
5	CC1 (2)	CC1-45 MHz	"M 5" (2)
6	CC1 (3)	CC1-45 MHz	"M 6" (2)
7	CC1 (4)	CC1-45 MHz	"M 7" (2)

Table 5-1. 900 MHz Test Mode/Channel Selection

(1) CC1-CC4 are control channels programmed in association with the selected trunking system.

(2) M stands for modulation type (0-3), see Table 5-2.

* Channel numbers 4 through 7 do not apply to LTR Models.

Test Mode/Tx Modulation

Test Mode/Tx Modulation

т

Use PTT switch for modulation type selection. A continuous press will advance the radio to the next modulation test (cyclic scroll) and perform Tx test till PTT is released. The modulation selection is described in the table below.

Modulation Type	Internal Speaker Audio Signaling	Internal Microphone Status	Display
CSQ	None	On	"0 C" (1)
Low Speed	None	On	"1 C" (1)
High Speed	Call Back	Off	"2 C" (1)
DTMF "#"	DTMF "#"	Off	"3 C" (1)

Table 5-2. Test Mode/Tx Modulation

* C stands for the selected channel (1-7) see Table 5-1.

Fail Mode

The radio will enter Fail Mode upon detecting one of the following errors:

- Application start-up self check error
- Codeplug information check error

There are two categories of errors: critical and non-critical. Critical errors will stop radio normal operation. Non-critical errors will be temporarily indicated as described in the table below.

Exiting Test Mode

To exit Test Mode, proceed as follows:

- Turn radio off.
- Turn RIB on.
- Turn radio on.

Error number	Failure Description	Display	Critical	Tone Sound
1	Internal RAM	Fatal 01	Yes	Illegal tone
2	External RAM	Fatal 02	Yes	Illegal tone
	Reserved			
	Reserved			
5	Flash checksum	Fatal 05	Yes	Illegal tone
6	Codeplug checksum	Error 06	Yes	Illegal tone
7 (1)	Codeplug personality	Error 06	No	Illegal Tone (when selected personality has checksum error)
8	Codeplug tuning error	Error 06	Yes	Illegal tone

Table 5-3.Fail Mode

(1) For error no. 7, personality (system) change is allowed although the illegal tone is heard. For error no. 8 the temporary illegal tone is heard. (See the Quick Start card for instructions on how to change personality.) To exit fail mode, power radio off.

Performance Checks

TEST NAME	COMMUNICATION ANALYZER	RADIO	TEST SET	COMMENTS
Reference Frequency	Mode: PWR MON 2nd channel test frequency Monitor. Frequency error input at RF In/Out	TEST MODE, Display: 2 0	PTT to continuous (during the performance check)	Frequency error to be < 700 Hz
Power RF	Same as Above	TEST MODE, Display: 2 0	Same as Above	Refer to Maintenance Specification Page IX
Voice Modulation	Mode: PWR MON 4th channel test frequency atten to -70, input to rf In/Out Monitor: DVM, AC Volts Set 1kHz mod Out level for 0.025Vrms at test set, 80mVrms at AC/DC test set jack.	TEST MODE, Display: 2 0	Same as Above, meter selector to mic	Deviation: 800 MHz: 3.6 kHz but 5.0 kHz 900 MHz: 2.5 kHz
Low-Speed Data Modulation 800/900	Same as Above	TEST MODE, Display: 2 1	PTT to continuous (during the performance check)	Deviation: <i>800 MHz:</i> <i>800 Hz but</i> 1200 Hz <i>900 MHz:</i> <i>350 Hz</i> 650 Hz
Voice Modulation (Internal)	Mode: PWR MON 2nd channel test frequency atten to -70, input to RF In/Out	TEST MODE, Display: 2 0	Remove modulation input	Press PTT switch on radio. Say "four" loudly into the radio mic. Measure deviation: 800 MHz: 3.8 kHz but 5.0 kHz 900 MHz: 2.5 kHz
High-Speed Data Modulation	Same as Above	TEST MODE, Display: 2 2	PTT to continuous (during the performance check)	Deviation: 800 MHz: 2.3 kHz but 3.8 kHz 900 MHz: 1.2 kHz but 2 kHz
DTMF Modulation (# SIGN)	Same as Above 2nd channel test frequency	TEST MODE, Display: 2 3 output at antenna	Same as Above	Deviation: 800 MHz: 2.8 kHz but 3.8 kHz 900 MHz: 1.4 kHz but 1.9 kHz
PL/DPL Modulation (radios with conventional coded squelch operation only)	Change frequency to a conventional transmit frequency, BW to narrow	Conventional coded squelch personality	Same as Above	Deviation: 800 MHz: 500 Hz but 1000 Hz 900 MHz: 250 Hz but 500 Hz
Talk-around Modulation (radios with conventional talk-around operation only)	Change frequency to conventional talk-around frequency. Mode:PWR MON deviation, attenuation to -70, input to RF In/Out Monitor: DVM, AC volts Set 1kHz Mod Out level for 25mVrms at test set.	Conventional talk- around personality	Same as Above	Deviation: 800 MHz: 3.8 kHz but 5.0 kHz 900 MHz: 1.9 kHz but 2.45 kHz

Table 5-4 Transmitter Performance Checks

Performance Checks

TEST NAME	COMMUNICATION ANALYZER	RADIO	TEST SET	COMMENTS
Rated Audio	Mode: GEN Output level: 1.0mV RF 1st Channel test frequency Mod: 1 kHz tone at 3 kHz deviation Monitor: DVM: AC Volts	TEST MODE, Channel 0 Modulation Type 1	PTT to OFF (center), meter to Audio PA	Set volume control to 2.84 Vrms
Distortion	Same as above, except for distortion	Same as Above	Same as Above	Distortion <5.0%
Sensitivity (SINAD)	Same as above, except SINAD, lower the rf level for 12 dB SINAD	Same as Above	PTT to OFF (center)	RF input to be <0.35 μV
Noise Squelch Threshold (only radios with conventional	RF level set to 1mV RF	Same as Above	PTT to OFF (center), meter selection to Audio PA, spkr/load to speaker	Set volume control to 2.84 Vrms
system need to be tested	As above, except change frequency to a conventional system. Raise RF level from Zero until radio unsquelches.	out of TEST MODE, select a conventional system	Same as Above	Unsquelch to occur at <0.3 µV Preferred SINAD=<12 dB

 Table 5-5.
 Receiver Performance Checks

Introduction

This section of the manual describes preventive maintenance, safe handling of CMOS devices, and repair procedures and techniques. Each of these topics provides information vital to the successful operation and maintenance of your radio.

Preventive Maintenance

GTX, GTX LTR, and LTS2000 radios do not require a scheduled preventive maintenance program; however, periodic visual inspection and cleaning is recommended.

Inspection

Check that the external surfaces of the radio are clean, and that all external controls and switches are functional. A detailed inspection of the interior electronic circuitry is neither needed nor desired.

Cleaning

The following procedures describe the recommended cleaning agents and the methods to be used when cleaning the external and internal surfaces of the radio. External surfaces include the front cover, housing assembly, and battery case. These surfaces should be cleaned whenever a periodic visual inspection reveals the presence of smudges, grease, and/or grime. Internal surfaces should be cleaned only when the radio is disassembled for servicing or repair.

The only recommended agent for cleaning the external radio surfaces is a 0.5% solution of a mild dishwashing detergent, such as $JOY^{\textcircled{o}}$, in water. The only factory recommended liquid for cleaning the printed circuit boards and their components is isopropyl alcohol (70% by volume).

CAUTION

The effects of certain chemicals and their vapors have harmful results on certain plastics. Aerosol sprays, tuner cleaners, and other chemicals should be avoided.

Cleaning External Plastic Surfaces

The detergent-water solution should be applied sparingly with a stiff, non-metallic, short-bristled brush to work all loose dirt away from the radio. A soft, absorbent, lintless cloth or tissue should be used to remove the solution and dry the radio. Make sure that no water remains entrapped near the connectors, cracks, or crevices.

Cleaning Internal Circuit Boards and Components

Isopropyl alcohol may be applied with a stiff, nonmetallic, short-bristled brush to dislodge embedded or caked materials located in hard-to-reach areas. The brush stroke should direct the dislodged material out and away from the inside of the radio.

Alcohol is a high-wetting liquid and can carry contamination into unwanted places if an excessive quantity is used. Make sure that controls or tunable components are not soaked with the liquid. Do not use high-pressure air to hasten the drying process, since this could cause the liquid to puddle and collect in unwanted places.

Upon completion of the cleaning process, use a soft, absorbent, lintless cloth to dry the area. Do not brush or apply any isopropyl alcohol to the frame, front cover, or back cover.

> **NOTE** Always use a fresh supply of alcohol and a clean container to prevent contamination by dissolved material (from previous usage).

Safe Handling of CMOS Devices

Complementary metal-oxide semiconductor (CMOS) devices are used in this family of radios. While the attributes of CMOS are many, their characteristics make them susceptible to damage by electrostatic or

Repair Procedures and Techniques

high voltage charges. Damage can be latent, resulting in failures occurring weeks or months later. Therefore, special precautions must be taken to prevent device damage during disassembly, troubleshooting, and repair. Handling precautions are mandatory for CMOS circuits and are especially important in low humidity conditions. DO NOT attempt to disassemble the radio without first referring to the CMOS CAUTION paragraph in the Disassembly and Reassembly section of the manual.

Repair Procedures and Techniques

Refer to the Disassembly and Reassembly section of the manual for pertinent information prior to replacing and substituting parts.

General

Parts Replacement and Substitution

Special care should be taken to be as certain as possible that a suspected component is actually the one at fault. This special care will eliminate unnecessary unsoldering and removal of parts, which could damage or weaken other components or the printed circuit board itself.

When damaged parts are replaced, identical parts should be used. If the identical replacement component is not locally available, check the parts list for the proper Motorola part number and order the component from the nearest Motorola Communications Parts office listed in the "Replacement Parts Ordering" section of this manual.

Rigid Circuit Boards

This family of radios uses bonded, multi-layer, printed circuit boards. Since the inner layers are not accessible, some special considerations are required when soldering and unsoldering components. The printedthrough holes may interconnect multiple layers of the printed circuit. Therefore, care should be exercised to avoid pulling the plated circuit out of the hole.

When soldering near the 28-pin connector, use care to avoid accidentally getting solder in the connector. Also, be careful not to form solder bridges between the connector pins. Closely examine your work for shorts due to solder bridges.

Chip Components

Use either the RLN4062 Hot-Air Repair Station or the Motorola 0180381B45 Repair Station for chip component replacement. When using the 0180381B45 Repair Station, select the TJ-65 mini-thermojet hand piece. On either unit, adjust the temperature control to 700° F (370° C), and adjust the airflow to a minimum setting. Airflow can vary due to component density.

- 1. To remove a chip component, select a hot-air hand piece and position the nozzle of the hand piece approximately 1/8" above the component to be removed. Begin applying the hot air. Once the solder reflows, remove the component using a pair of tweezers. Using solder wick and a soldering iron or a power desoldering station, remove the excess solder from the pads.
- 2. To replace a chip component using a soldering iron, select the appropriate micro-tipped soldering iron and apply fresh solder to one of the solder pads. Using a pair of tweezers, position the new chip component in place while heating the fresh solder. Once solder wicks onto the new component, remove the heat from the solder. Heat the remaining pad with the soldering iron and apply solder until it wicks to the component. If necessary, touch up the first side. All solder joints should be smooth and shiny.
- 3. To replace a chip component using hot air, select the hot-air hand piece and reflow the solder on the solder pads to smooth it. Apply a drop of solder paste flux to each pad. Using a pair of tweezers, position the new component in place. Position the hot- air hand piece approximately 1/8" above the component and begin applying heat. Once the solder wicks to the component, remove the heat and inspect the repair. All joints should be smooth and shiny.

Over-Molded Pad-Array Carrier (OMPAC)

CAUTION

ASFIC U701 is an OMPAC. It must be kept in a sealed bag with desiccant in the bag (in a "dry box" as supplied by the Motorola Parts Department prior to use. If the OMPAC is ambient for an unknown amount of time or for more than 96 hours, then it must be baked for at least eight hours at 260 ° F (185° C).

CAUTION

If neighboring OMPAC components are heated above 365° F (185° C), they will suffer die-bond delamination and possible "popcorn" failure.

During all repair procedures, heating neighboring components can be minimized by:

- Using upper heat only. using the correct size heat-focus head, approximately the same size as the carrier being replaced.
- Keeping the heat-focus head approximately 1/ 8" (0.3cm) above the printed circuit board when removing or replacing the device.
- To remove the OMPAC, select the R-1319A 1. Air-Flow Station and the appropriate heatfocus head (approximately the same size as the OMPAC. Attach the heat-focus head to the chimney heater. Adjust the temperature control to approximately 415° F (215° C) 445° F (230° C) maximum. Adjust the airflow slightly above the minimum setting. Apply the solder paste flux around the edge of the OMPAC. Place the circuit board in the R-1319AR-1319A's circuit board holder, and position the OMPAC under the heat-focus head. Lower the vacuum tip and attach it to the OMPAC by turning on the vacuum pump. Lower the heat-focus head until it is approximately 1/8" (0.3cm) above the carrier. Turn on the heater and wait until the OMPAC lifts off the circuit board. Once the part is off, grab it with a pair of tweezers and turn off the vacuum pump. Remove the circuit board from the R-1319AR-1319A's circuit board holder.
- 2. To replace the OMPAC, the solder pads on the board must first be cleaned of all solder to ensure alignment of the new chip carrier. Prepare the sight by using solder wick and a soldering iron to remove all solder from the solder pads on the circuit board. If a power desoldering tool is available, it can be used instead of the solder wick. Clean the solder pads with alcohol and a small brush. Dry and inspect. Ensure that all solder is removed.

Once the preparation is complete, place the circuit board back in the R-1319A's circuit board holder. Add solder paste flux in the trench of the flux block and spread it using a one-inch putty knife. Flux the OMPAC by placing it in the trench of the flux block. Once the flux is applied, place the OMPAC on the circuit board, making certain that it is oriented correctly on the board. Position the heat-focus head over the OMPAC and lower it to approx-

imately 1/8" (0.3cm) over the carrier. Using the same heat and airflow setting used to remove the OMPAC, turn on the heater and wait for the carrier to reflow (heating and reflow should take longer than 60 seconds).

Once the carrier reflows, raise the heat-focus head and wait approximately one minute for the part to cool. Remove the circuit board and inspect the repair. No cleaning should be necessary.

Shields

1. Removing and replacing the shields will be done with the R-1319A, using the same heat and airflow profile used to remove and replace OMPAC components.

Place the circuit board in the R-1319A's holder. Select the proper heat focus head and attach it to the heater chimney. Add solder paste flux around the base of the shield. Position the shield under the heat-focus head. Lower the vacuum tip and attach it to the shield by turning on the vacuum pump. Lower the focus head until it is approximately 1/8"(0.3cm) above the shield. Turn on the heater and wait until the shield lifts off the circuit board. Once the shield is off, turn off the heat, grab the part with a pair of tweezers, and turn off the vacuum pump. Remove the circuit board from the R-1319A's circuit board holder.

2. To replace the shield, add solder to the shield if necessary, using a micro-tipped soldering iron. Next, rub the soldering iron tip along the edge of the shield to smooth out any excess solder. Use solder wick and a soldering iron to remove excess solder from the solder pads on the circuit board. Place the circuit board back in the R-1319A's circuit board holder. Place the shield on the circuit board using a pair of tweezers. Position the heat-focus head over the shield and lower it to approximately 1/8" above the shield. Turn on the heater and wait for the solder to reflow.

Once complete, turn off the heat, raise the heatfocus head, and wait approximately one minute for the part to cool. Remove the circuit board and inspect the repair. No cleaning should be necessary.
